Abstract

AudioMulch is software for real-time sound synthesis, music composition and performance-oriented audio processing. Version 1.0 of the software was released in February 2006 after an extended beta testing period spanning over 8 years. Following this release a new development cycle was commenced under the "AudioMulch 2006" project moniker.

This report presents as-yet unreleased work undertaken since version 1.0, including the port to Trolltech's Qt GUI toolkit, a new interactive patching user interface, and microtonal tuning table support. Successes and challenges encountered during the process of development are examined. During the project period collaborations with performers, composers, designers and audio engineers were undertaken to improve the software in various ways. The results of these collaborations are also discussed.

AudioMulch 2006 development activities were partially supported by The Australia Council for the Arts' "Sounding Out" instrument builders initiative, and by Arts Victoria.
